

Comparison with OKTA ASA & CyberArk

This is a datasheet that
provides comparison of
AuthNull with OKTA
Advanced Server Access &
CyberArk

Passwordless Privileged Access
Management

Passwordless PAM

AuthNull replaces traditional PAM with a Passwordless solution.

AuthNull enables access to server infrastructure without passwords, or SSH Keys.

Passwordless Authentication

AuthNull enables passwordless authentication by supporting LDAP 1FA or 2FA, Posix account logins with 1FA or 2FA, additionally through protocols such as SSH, VNC, RDP, Telnet and more.

All credentials are stored as a decentralized identity credentials eliminating the need for a vault.

What is the best way to reduce the most critical attack surface of credentials? By removing it of course!

How does AuthNull compare with OKTA?

The biggest credential breach during the pandemic was shared credentials. OKTA does not fully eliminate a central attack surface and still relies on a Certificate authority.

While this can be claimed as “passwordless”, and “ephemeral”.. the fact is that this requires users to be logged in and allowing their workstations to trust their CA.

This makes the OKTA certificate authority a biggest attack surface. Removing the CA is the best way to secure a system and that is what AuthNull has done,

AuthNull enables organizations to truly deploy Zero trust, passwordless security to access critical infrastructure.

How does AuthNull compare with CyberArk?

CyberArk is most well known of PAM solutions. CyberArk is a traditional PAM system with high friction and takes weeks, if not months to rollout.

While CyberArk offers full versatility in terms of features, it is operationally intensive.

Organizations that are just getting started with PAM and are used to the current generation SAAS platforms may find CyberArk overwhelming, bloated and hard to use.

What customers say about CyberArk –

AuthNull enables organizations to truly deploy

AuthNull PAM

AuthNull is a next-gen PAM platform

AuthNull is a drop-in replacement for legacy PAM solutions while providing simplified passwordless authentication to access server infrastructure

Session Management and Recording

Get full video and text recording of your sessions.

[Learn more](#)

Credential Authentication - 1FA or 2FA

AuthNull provides 1FA, 2FA credential authentication for local and LDAP users respectively.

[Learn more](#)

Endpoint Management

AuthNull's endpoint agent supports endpoint management - user synchronization, user and group discovery and synchronization, services installation, authentication configuration and more.

[Learn more](#)

Tamper evident credentials.

AuthNull provides tamper evident identities and credential transactions using decentralized identity and optional blockchain based immutable addresses.

Features include.

Session Video Recording

All sessions going through the web console are automatically and fully recorded.

Text Recording

All sessions regardless of direct SSH connections, or going through a web console are fully recorded using a text recording feature.

Authentication logs

Authentication logs from each server is automatically available on the SIEM solution of your choice, or on a ELK console on AuthNull.

Passwordless 1FA

Passwordless access for local privileged accounts. No SSH Keys, Passwords - rotation and distribution needed. All sessions are validated with two roots of trust, require decentralized credentials stored on Wallet protected by users' bioetrics.

LDAP Account authentication with Passwordless as 2nd Factor

LDAP accounts can be logged in with Passwordless 2nd Factor, with JIT SSH Keys generated during user checkout.

Local privileged accounts - JIT privileged escalation

Local privileged users can be checked out with escalated privileges Just In Time (JIT) with automated expiry of credentials.

It is very clear that existing CyberArk customers consider it as a very bloated and a cumbersome solution to implement. The fact that CyberArk has a professional services arm and encourages customers to leverage it to implement the solution adds fuel to the fire of the belief that it is intentionally more complicated than it needs to be, and incurs in significant IT spend to implement.

How is AuthNull Different?

AuthNull is built from ground up to be simple AuthNull has the right combination of features that really matter, removing all the bloat that is not needed.

AuthNull uses passwordless and comes with a wallet app that enables passwordless Authentication. This app also eliminates a centralized vault as Authnull provides the same functionality through decentralized credentials and the wallet app These decentralized credentials are stored in the users wallet as opposed to a central vault eliminating a major attack vector.

Feature	OKTA Advanced Server Access	AuthNull	Cyberark
Login client	Custom, SSH client	VNC, SSH, RDP – no custom clients	VNC, SSH, RDP – no custom clients
Passwordless approach	Centralized, ephemeral CA	Decentralized credentials and identity	Centralized + Ephemeral CA
Existing passwords and SSH keys supported	No	Supported for legacy reasons	Supported
Windows support	Yes	Yes (upcoming)	Yes
Linux Support	Yes	Yes	Yes
Blockchain based tamper evident credentials	No	Yes	Yes
Blockchain hash logging	No	Yes	No
Authenticator	OKTA Authenticator App	AuthNull Authenticator /Wallet App	CyberArk authenticator app
FaceID to protect credentials	Yes	Yes	Yes
SSO console depends on passwords	Yes, OKTA SSO	Yes, OKTA SSO	Yes, OKTA SSO
End user console	Yes	Yes	Yes
Extensive logging	Yes	Yes	Yes
Built in runtime guardrails	No	Yes	No
No	No	No	No
Self rotating credentials	No	Yes	No
Agent for PAM	Yes	Yes	Yes
AD authentication	No	Yes	Yes
Passwordless SSH Login	Yes	Yes	Yes
